

# CS 180 - Intro to C++

Note Title

8/20/2010

## Announcements

- HW 1 out - due next Wednesday  
by 10am

# A comparison:

## Python

```
def gcd(u, v):
    # we will use Euclid's algorithm
    # for computing the GCD
    while v != 0:
        r = u % v    # compute remainder
        u = v
        v = r
    return u

if __name__ == '__main__':
    a = int(raw_input('First value: '))
    b = int(raw_input('Second value: '))
    print 'gcd:', gcd(a,b)
```

## C++:

```
#include <iostream>
using namespace std;

int gcd(int u, int v) {
    /* We will use Euclid's algorithm
    for computing the GCD */
    int r;
    while (v != 0) {
        r = u % v;    // compute remainder
        u = v;
        v = r;
    }
    return u;
}

int main( ) {
    int a, b;
    cout << "First value: ";
    cin >> a;
    cout << "Second value: ";
    cin >> b;
    cout << "gcd: " << gcd(a,b) << endl;
    return 0;
}
```

White space is irrelevant!

```
int gcd(int u, int v) { int r; while (v != 0) { r = u % v; u = v; v = r; } return u; }
```

Python used returns & indentation to separate commands & loops.

(Please continue to indent!)

- ; in C++ is like a return in Python
- { } tell what is inside a loop, function, ...

## Executing code

In Python, we could save the code as gcd.py & then type "python gcd.py" to run it.

In C++:

- Save as gcd.cpp

Compile - - type "g++ -o gcd gcd.cpp"   
 *program that compiles*

run program - - type "./gcd"

# Data Types

C++ Type	Description	Literals	Python analog
<b>bool</b>	logical value	<b>true</b> <b>false</b>	<b>bool</b>
<b>short</b>	integer (often 16 bits)		
<b>int</b>	integer (often 32 bits)	39	
<b>long</b>	integer (often 32 or 64 bits)	39L	<b>int</b>
—	integer (arbitrary-precision)		<b>long</b>
<b>float</b>	floating-point (often 32 bits)	3.14f	
<b>double</b>	floating-point (often 64 bits)	3.14	<b>float</b>
<b>char</b>	single character	'a'	
<b>string<sup>a</sup></b>	character sequence	"Hello"	<b>str</b>

## Data Types (cont.)

- Each integer type can also be unsigned.

Instead of ranging from  $-(2^{b-1})$  to  $(2^{b-1}-1)$   
goes from 0 to  $2^b-1$ .

int number;  $\leftarrow$  go up to  $2^{31}-1$

unsigned int number2;  $2^{32}-1$

## Char versus string

```
char a;  
a = 'a';  
a = 'h';
```

chars use  
single quotes!

```
(import string library)  
String word;  
word = "CS 180";
```

← double quotes

Strings are not automatically included!  
They are standard in most libraries,  
but need to import that library.

# Strings

Syntax	Semantics
s.size( ) s.length( )	Either form returns the number of characters in string s.
s.empty( )	Returns <b>true</b> if s is an empty string, <b>false</b> otherwise.
s[index]	Returns the character of string s at the given index (unpredictable when index is out of range).
s.at(index)	Returns the character of string s at the given index (throws exception when index is out of range).
s == t	Returns <b>true</b> if strings s and t have same contents, <b>false</b> otherwise.
s < t	Returns <b>true</b> if s is lexicographical less than t, <b>false</b> otherwise.
s.compare(t)	Returns a negative value if string s is lexicographical less than string t, zero if equal, and a positive value if s is greater than t.
s.find(pattern) s.find(pattern, pos)	Returns the least index (greater than or equal to index pos, if given), at which pattern begins; returns <b>string::npos</b> if not found.
s.rfind(pattern) s.rfind(pattern, pos)	Returns the greatest index (less than or equal to index pos, if given) at which pattern begins; returns <b>string::npos</b> if not found.
s.find_first_of(charset) s.find_first_of(charset, pos)	Returns the least index (greater than or equal to index pos, if given) at which a character of the indicated string charset is found; returns <b>string::npos</b> if not found.
s.find_last_of(charset) s.find_last_of(charset, pos)	Returns the greatest index (less than or equal to index pos, if given) at which a character of the indicated string charset is found; returns <b>string::npos</b> if not found.
s + t	Returns a concatenation of strings s and t.
s.substr(start)	Returns the substring from index start through the end.
s.substr(start, num)	Returns the substring from index start, continuing num characters.
s.c_str( )	Returns a C-style character array representing the same sequence of characters as s.
