

## Review questions for midterm

1. What is a regular expression? What is a DFA/NFA? (See questions on the homework relating to these concepts.)
2. What is a context free grammar? (Again, see homework questions.)
3. What is Chomsky Normal Form, and why do we care about it? How do you put something in CNF? (Again, see homework.)
4. What is a LL grammar? What is an LR grammar? Why are they useful?
5. What is lex/flex? (Recall basic rules, etc.)
6. What is the goal of tokenizing? Why is it done separately from parsing?
7. What is the big-O complexity of parsing? (Hint: there isn't one answer to this one.)
8. What is the difference between top down and bottom up parsing?
9. What is binding time?
10. What is the advantage of binding as early as possible? Why do we delay bindings despite this in some languages?
11. What do lifetime and visibility mean in the context of binding?
12. What do we mean by the scope of a binding?
13. What is dynamic scoping (versus static scoping)?
14. What is elaboration?
15. What is a closed scope?
16. What does the use of dynamic scoping imply the need for run-time type checking?
17. What are aliases, and why can they be a problem in language design and implementation?
18. Explain the differences (and similarities) between overloading, coercion, and polymorphism. Give an example of each of them in a programming language.

19. Problem 3.5 and 3.6 in the textbook (page 165)
20. Problem 3.11 on page 167
21. What is the difference between the reference model of variables and the value model? Why is the distinction so important? Give examples of languages that use each model.
22. What is an l-value? An r-value?
23. Why is the distinction between mutable and immutable variables so important in a language with a reference model for variables? (Hint: Think Python.)
24. List the main uses for goto, and the (much better) alternatives for each.
25. What is a continuation?
26. Why do languages provide case statements if they already have if-then-else statements?
27. Why do many languages require that the step size of an enumeration controlled loop be a compile-time constant? In a similar vein, why do languages not allow the bounds of increment of an enumeration controlled loop to be floating-point numbers?
28. What are the advantages and disadvantages of making the index variable local to the loop it controls?
29. What is tail-recursion, and why is it important?
30. What is lazy evaluation? When is it used, and why? Give an example of a language where it is used.
31. Define and compare/contrast the following: strongly typed, statically typed, dynamically typed, weakly typed
32. Give two examples of languages that lack a boolean type. What do they use instead? What are some advantages and disadvantages of this model?
33. What is the difference between type equivalence and type compatibility?
34. What are structural and name equivalence? Discuss comparative advantages, and give examples of languages that use each.
35. What are strict and loose name equivalence?

36. Under what circumstances does a type conversion require a run-time check? Give at least 2 examples.
37. What are “holes” in records? When do they arise, and what are the strategies that are used to minimize the problems they cause?
38. Under what circumstances can an array declared within a subroutine be allocated in the stack? Under what circumstances can it be allocated in the heap?
39. Compare continuous and row-pointer layout for arrays.
40. What is the difference between row-major and column-major layouts of arrays, and why should a programmer care which one is used?
41. Why might languages treat strings differently than generic arrays? Give at least 3 examples of this.
42. Discuss the advantages and disadvantages of interoperability of pointers and arrays in C.
43. What are dangling references? When are they created, and why are they a problem?
44. What is garbage collecting? Describe the reference count model of garbage collecting, and explain briefly why it doesn't always work.
45. Why was automatic garbage collection so slow to be adopted by modern programming languages? (In other words, what are the disadvantages of automatic garbage collection?)
46. Most statically typed languages since the 1970s (like Java and C#) use some form of name equivalence. Is structural equivalence a bad idea? Why or why not?
