

# CS 180: Data Structures, Spring 2018

## Homework 3

Due *via git* on Friday, Feb. 9

For this program, you'll modify the `SLinkedList.h` and `SLinkedList.cpp` files that are posted on the schedule page and checked into the course git repository; *all* of the problems are designed to be added to that class. In addition, I've posted `testSLL.cpp`, which is a (very simple) test file for the class; you are welcome to download and modify it as well for your test file. Please don't forget to add appropriate comments to the functions and to the main, as well; these are required in all programs from here on out!

1. Write a function `size` which takes no input arguments and returns an integer which is the size of the linked list.
2. Write a function `getLast` which takes no inputs and returns the value stored in the last element of the list. If the list is empty, throw an appropriate error.
3. Write a function `maximum` that takes no input parameters and returns the maximum value stored in any node of your linked list.
4. Write the `operator=` function for the `SLinkedList` class. Be sure to make a deep copy and deallocate any memory that is no longer needed.
5. Finally, write a main function to test all of your functions. Please comment and output appropriately, so that by looking at your code and running your main, we can see exactly where and how you are testing each problem.
6. Extra credit: Write a *fast* algorithm for reversing a singly linked list, so that the order of the nodes is the opposite of the original list. (Hint: You can do this in one pass through the list, but it will require some extra pointers to help you out.)
